

Objective: To understand priority queue implementations in Python including being able to determine the big-oh of each operation.

To start the lab: Download and unzip the lab4.zip file from eLearning.

Part A: Python list implementations of a Priority Queue

a) Suppose that we have a priority queue with integer priorities such that the smallest integer corresponds to the highest priority. For the following priority queue, which item would be dequeued next?

b) The `ListPriorityQueue` implementation in `lab4/list_priority_queue.py` uses an **unordered Python list**.

What would be the big-oh notation for each of the following methods: (justify your answer)

- enqueue:
- dequeue:

c) The `SortedListPriorityQueue` implementation in `lab4/sorted_list_priority_queue.py` uses a **Python list order by priorities** in descending order.

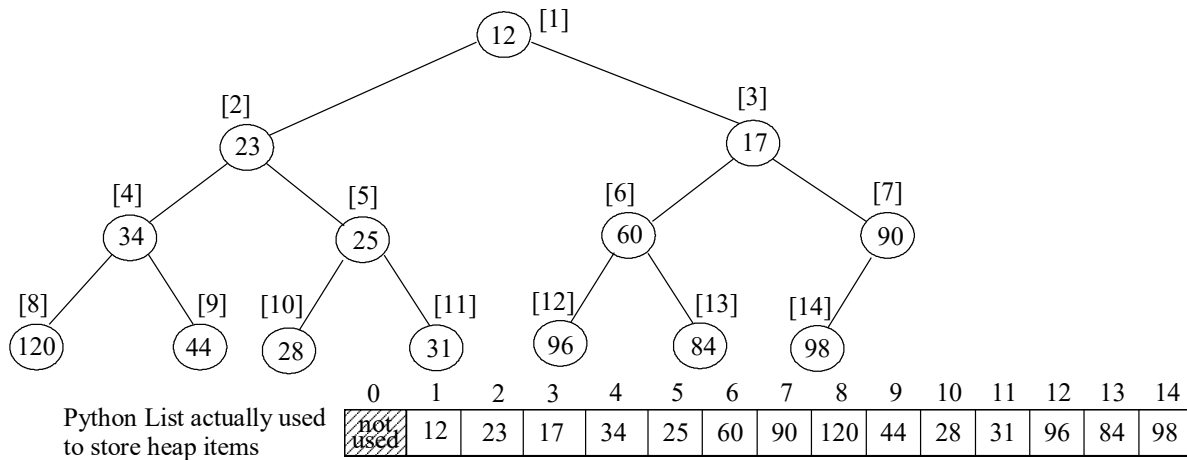

What would be the big-oh notation for each of the following methods: (justify your answer)

- enqueue:
- dequeue

d) Why would it be a bad idea to implement a priority queue using a **Python list order by priorities** in reverse (ascending) order? (HINT: What is the big-oh notations for enqueue and dequeue?)

Part B: (Lecture 7 and) Section 6.6 discusses a very “non-intuitive”, but powerful list/array-based approach to implement a priority queue, call a binary heap. The list/array is used to store a *complete binary tree* (a full tree with any additional leaves as far left as possible) with the items being arranged by *heap-order property*, i.e., each node is \leq either of its children. An example of a *min heap* “viewed” as a complete binary tree would be:

a) For the above heap, the list/array indexes are indicated in []'s. For a node at index i , what is the index of:

- its left child if it exists:
- its right child if it exists:
- its parent if it exists:

Recall the General Idea of `insert(newItem)`:

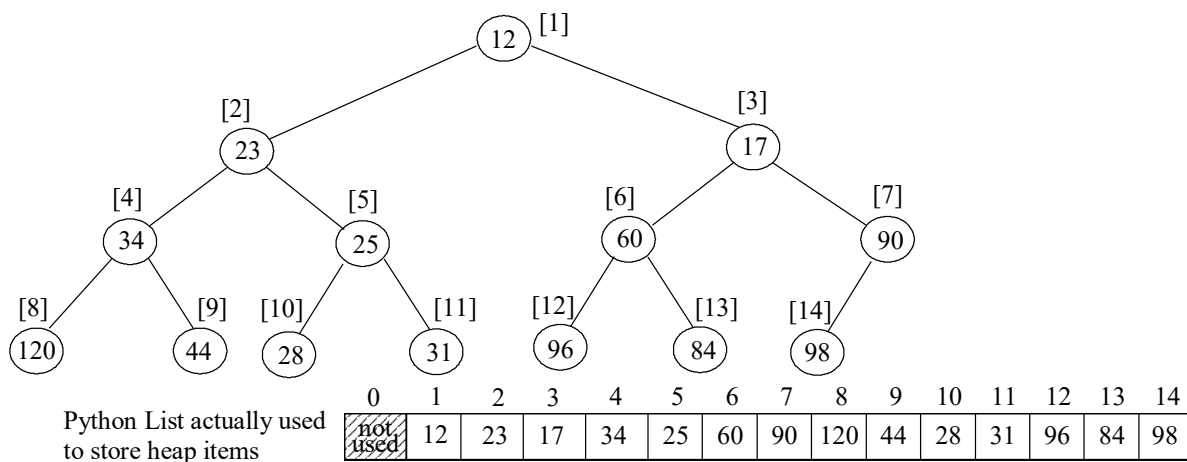

- append `newItem` to the end of the list (easy to do, but violates heap-order property)
- restore the heap-order property by repeatedly swapping the `newItem` with its parent until it *percolates up* to the correct spot

b) What would the above heap look like after inserting 18 and then 27? (show the changes on above tree)

c) What is the big-oh notation for inserting a new item in the heap?

Now let us consider the `delMin` operation that removes and returns the minimum item. Recall the General Idea of `delMin()`:

- remember the minimum value so it can be returned later (easy to find - at index 1)
- copy the last item in the list to the root, delete it from the right end, decrement size
- restore the heap-order property by repeatedly swapping this item with its smallest child until it *percolates down* to the correct spot
- return the minimum value

d) What would the above heap look like after `delMin`? (show the changes on above tree)

Part C: (a) Run the `lab4/timePriorityQueues.py` program that enqueues 40,000 random integers followed by dequeuing all 40,000 integers from various priority queues discussed above. Complete the following timing table from the output of `timePriorityQueues.py`.

Priority Queue Implementation	Execution Time in Seconds	
	Enqueuing 40,000 Random ints	Dequeuing 40,000 ints
Unsorted Python list		
Sorted Python list in descending order		
“Reverse” sorted Python list in ascending order		
Binary heap stored in a Python list		

b) Why does it take more time to enqueue 40,000 items in the “unsorted” Python list version than dequeue 40,000 in the sorted Python list version?

c) Why does it take more time to dequeue 40,000 items in the heap version than enqueue 40,000 in the heap version?

d) Why is the heap implementation of the priority queue considered “better” than the other three?

After you have answered all the questions, submit your answers on eLearning.

If you do not get done today, then submit it by next week’s lab period.

If you have extra time, this would be a good chance to work on Homework #2!
